

ABSTRACT OF THE DISCLOSURE

A method for inter-process communication between non-persistent application instances includes establishing a first non-persistent application instance serving a first party and establishing a second non-persistent application instance serving a second party. In the first application instance, an HTML page is generated having instructions for a persistent browser instance having received the HTML page to initiate a new application session for the second party. Thus, inter-application communication is possible where one non-persistent application instance is able to notify and/or interrupt another non-persistent application instance by way of an associated real time component (web browser or proxy browser).
